Conclusions

Smoothing in 2 dimensions

- ▶ Have some geographical region and wish to find out something about the biological population in it.
- ▶ Response is eg. animal distribution, wish to predict based on (x, y) and other covariates eg. habitat, size, sex, etc.
- ▶ This problem is relatively easy if the domain is simple.

Smoothing with GAMs

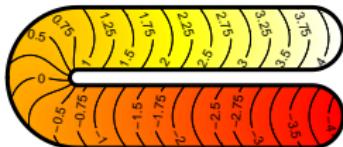

- ▶ Take a GLM, throw in some non-parametric components.
- ▶ Objective function takes the form:

$$\sum_{i=1}^n (z_i - f(x_i, y_i; \theta))^2 + \lambda \int_{\Omega} P f(x, y; \theta) d\Omega$$

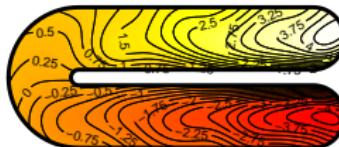

- ▶ f is the function you want to estimate, made up of basis functions, so $z_i = f(x_i, y_i; \theta) + \epsilon_i$.
- ▶ P is some penalty function, usually second squared derivative.

Smoothing over complex domains

- ▶ Smoothing of complex domains makes this a lot more difficult.
- ▶ Problem of leakage.
- ▶ Euclidean distance doesn't always make sense.
- ▶ Models need to incorporate information about the intrinsic structure of the domain.

Ramsay test function

Thin plate spline fit

Possible solutions to leakage problems

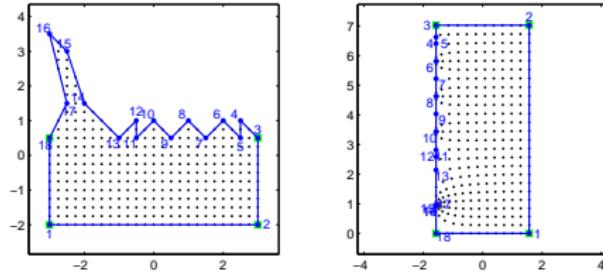

- ▶ FELSPLINE (Ramsay, (2002).)
- ▶ Within-area distance (Wang and Ranalli, (2007).)
- ▶ Soap film smoothers (Wood *et al.* (2008).)
- ▶ Domain morphing (me!)

Why morph the domain?

- ▶ Takes into account within-area distance.
- ▶ Gives a known domain that is easier to smooth over.
- ▶ Potentially less computationally intensive.

However:

- ▶ Don't maintain isotropy - distribution of points odd.
- ▶ Not clear what this does to the smoothness penalty.

Conclusions

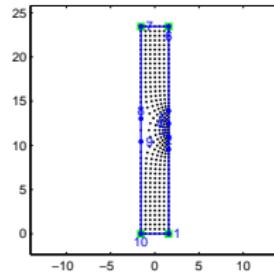

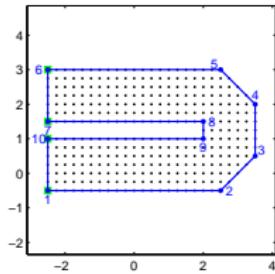

The Schwarz-Christoffel transform

- ▶ Take a polygon in some domain W and morph it to a new domain W^* .
- ▶ Do this by starting at the new domain and working back to the polygon.
- ▶ Can draw a polygonal bounding box around some arbitrary shape.

Schwarz-Christoffel algorithm

- ▶ Start with a rectangle.
- ▶ Add vertices.
- ▶ Iteratively deform by changing angles.
- ▶ Continue until the new shape is identical to the polygon.
- ▶ We then have a function for the mapping, $\varphi(x, y)$.
- ▶ $\varphi(x, y)$ is a conformal mapping.

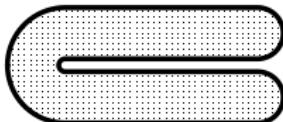

The mapping

- ▶ Use a bounding box around the horseshoe.

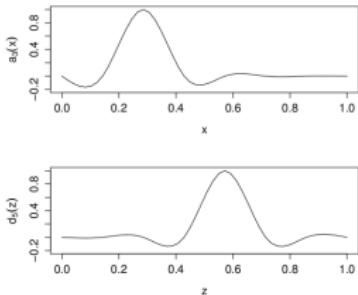

- ▶ Morphing the horseshoe shape still gives a slightly odd domain however, we are still doing better than before.

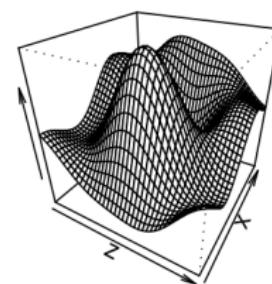

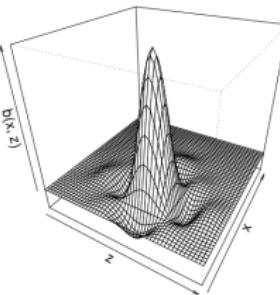

Results

- ▶ Fit using both thin plate regression splines and P-splines with a comparison to the soap film (current best.)
- ▶ MSE used to compare over a grid of prediction points.
- ▶ Transformation method does well on the first horseshoe.
- ▶ Not so well for the alternate horseshoe.

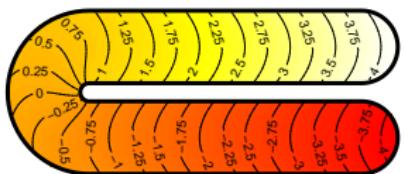

Tensor product

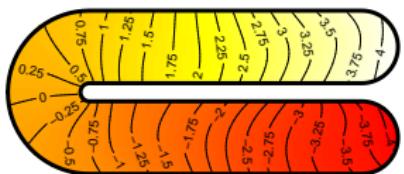

Thin plate

Horseshoe plots

Truth

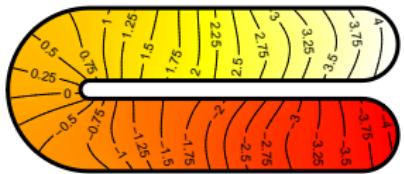

SC+PS

SC+TPRS

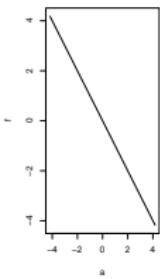

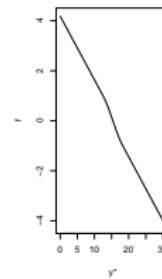

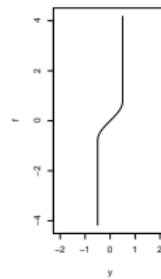

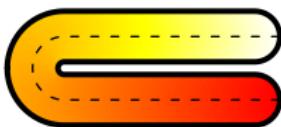

Soap film

Why does it do well?

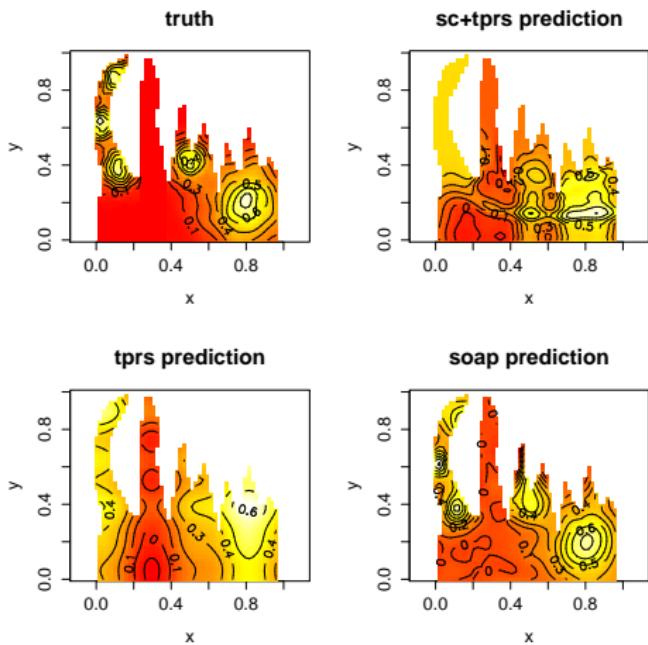

- ▶ Looking at line plots, we can see the difference in gradient.
- ▶ SC method seems to approximate the gradient better.

Problems

- ▶ Implementation is Matlab+R.
- ▶ Problems with more realistic situations:
 - ▶ Weird artifacts.
 - ▶ Arbitrary selection of vertices.
 - ▶ Morphing of domain appears to cause features to be smoothed over.

A more realistic domain

Conclusions

Multidimensional scaling and within-area distances

- ▶ Idea: use MDS to remap points in the domain according to their distance within the domain.
- ▶ First need to find the within area distances.
- ▶ Can then smooth over the mapped points.
- ▶ Prediction outside the original data is fine, since we can insert new points using: [[formula from Julian]]

Multidimensional scaling refresher

- ▶ First take the data matrix, X (here n by 2 for 2D case.)
- ▶ Double centre it (subtract row and column means.)
- ▶ XX^T
- ▶ Similar to principle components. [[diagram here of MDS-d set of coords]]

Finding within-area distances

- ▶ Use a new algorithm of Wood to find the within area distances. [[algorithm description here]]

Ramsey simulations

- ▶ again test on Ramsey's horseshoe. [lots of pics]

Other domains

- ▶ test on other domains [lots of pics]

Simulation Results

Conclusions

Conclusions

- ▶ Seems that the S-C transform does not have much utility.
- ▶ MDS shows more promise.
- ▶ MDS easier to transfer to higher dimensions.

Further work

- ▶ Real data!
